# Outline

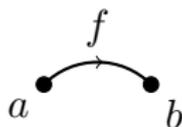

1. 2-categories
2. Three-dimensional topological quantum field theories
3. Presentation theorem
4. Modular tensor categories
5. Classification theorem
6. Sample calculations

# 1. 2-categories

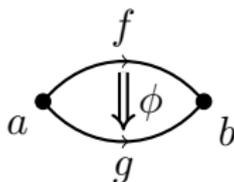

A **2-category** consists of *objects*, drawn as

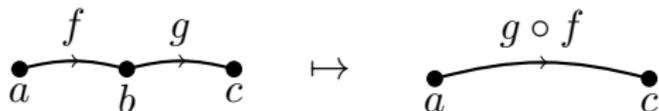

together with *1-morphisms*, drawn as

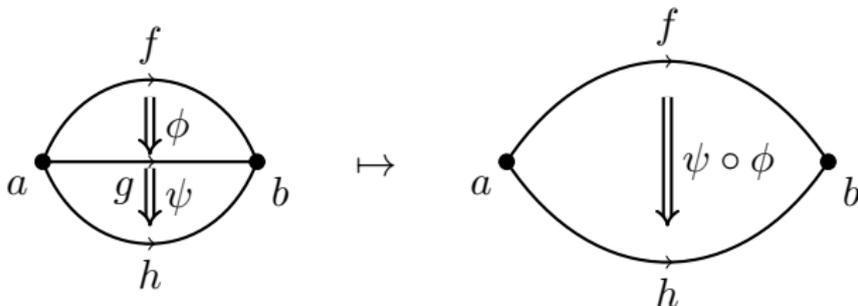

as well as *2-morphisms*, drawn as

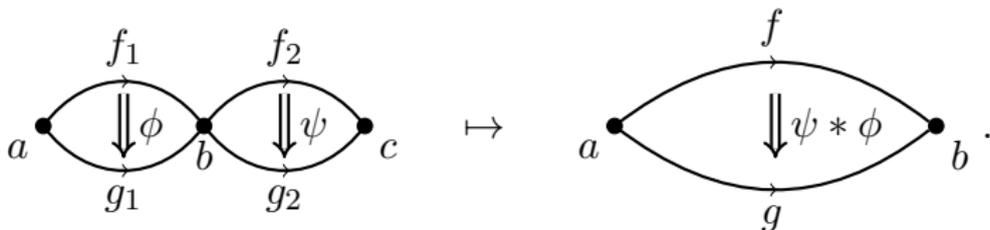

The 1-morphisms can be composed:

The 2-morphisms can be composed both *vertically*,

and *horizontally*,

These composition operations must satisfy various coherence equations.

Examples of 2-categories:

1. **Top**: objects are topological spaces, 1-morphisms are continuous maps, 2-morphisms are homotopies.
2. **Cat**: objects are categories, 1-morphisms are functors, 2-morphisms are natural transformations.
3. **Alg**: objects are algebras, 1-morphisms are bimodules, 2-morphisms are bimodule homomorphisms.
4. **LinCat**: objects are  $\mathbb{C}$ -linear categories, 1-morphisms are profunctors, 2-morphisms are natural transformations.
5. ... (any structure that has morphisms *between* the morphisms!)

## 2. Three-dimensional TQFTs

**Definition.** The oriented 1-2-3 bordism 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  is defined as follows:

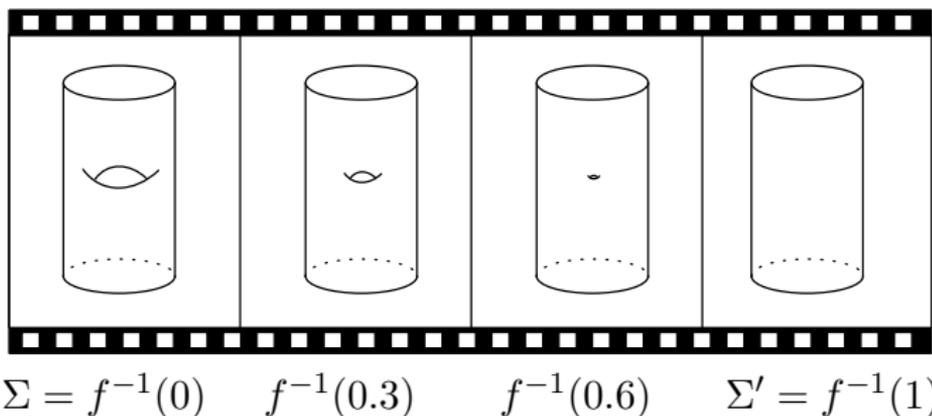

- ▶ An object is a closed oriented 1-manifold  $A$ , for example:

- ▶ A 1-morphism  $A \xrightarrow{\Sigma} B$  is a *bordism* from  $A$  to  $B$  (a compact oriented 2-manifold with  $\partial\Sigma \cong \overline{A} \amalg B$ ), for example:

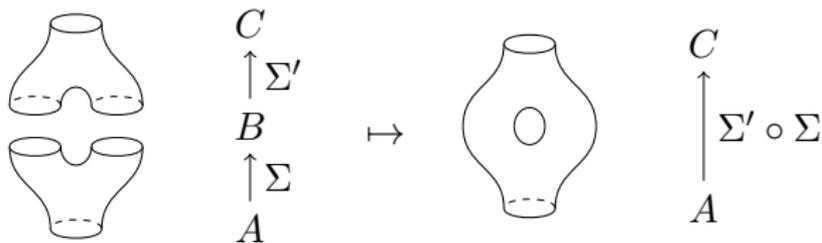

- A 2-morphism  $\Sigma \begin{matrix} \nearrow B \\ \xrightarrow{M} \\ \searrow A \end{matrix} \Sigma'$  is a 3-dimensional bordism from  $\Sigma$  to  $\Sigma'$ , for example:

We can visualize  $M$  as a 'movie' with the help of a Morse function  $f: M \rightarrow [0, 1]$  so that the fibers  $f^{-1}(t)$  interpolate from  $\Sigma$  to  $\Sigma'$ .

Composition of 1- and 2-morphisms is given by *gluing* the bordisms together, for example:

There is another composition operation — *disjoint union* of bordisms. This makes  $\mathbf{Bord}_{123}^{\text{or}}$  into a ‘symmetric monoidal 2-category’.

**Definition.** An oriented 123 topological quantum field theory is a symmetric monoidal 2-functor

$$Z: \mathbf{Bord}_{123}^{\text{or}} \rightarrow \mathbf{LinCat}.$$

### 3. Presentation theorem

**Theorem.** [BB, CD, CS-P, JV] The symmetric monoidal 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  has the following presentation:

- ▶ Generating objects:

- ▶ Generating 1-morphisms:

cap

cup

pants

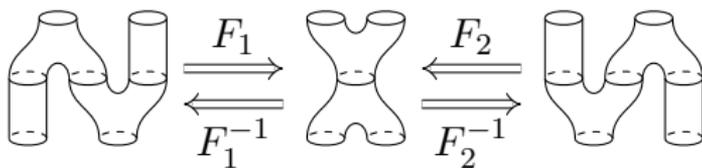

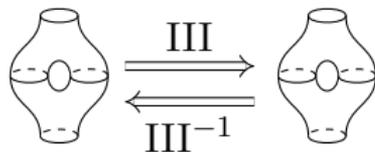

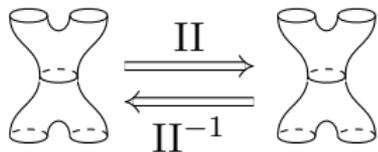

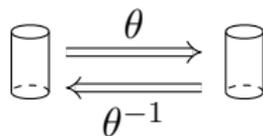

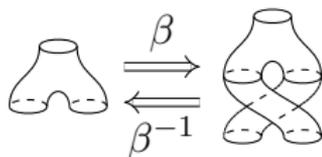

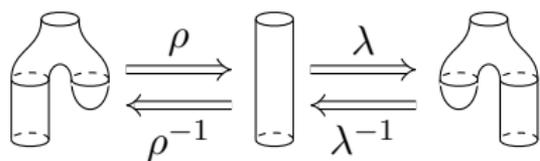

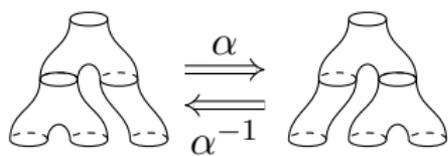

copants

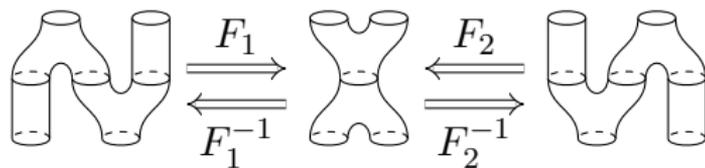

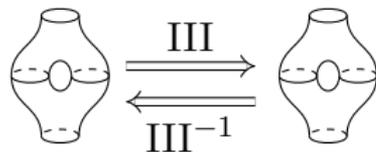

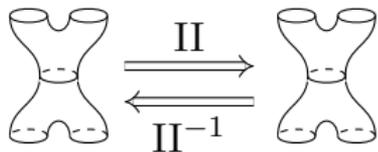

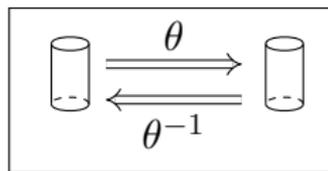

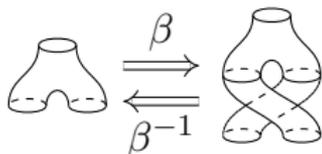

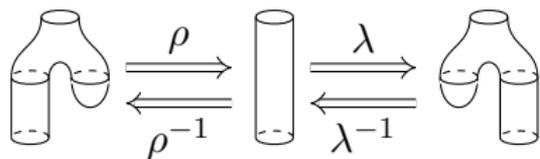

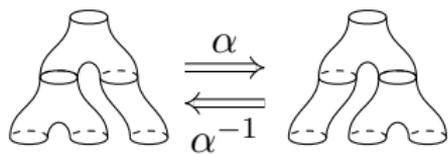

- ▶ Generating 2-morphisms:

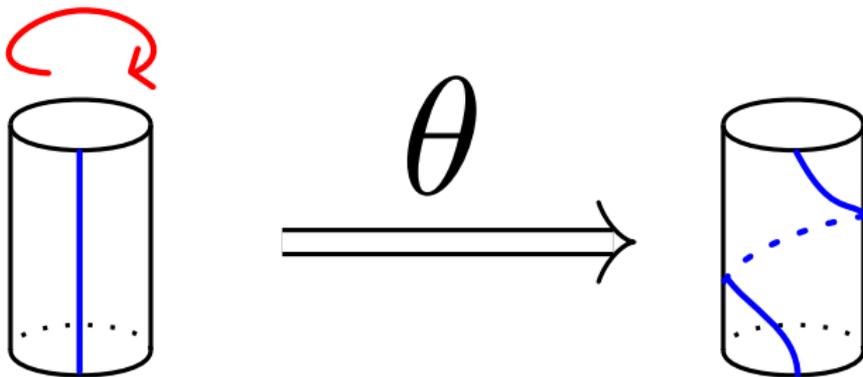

...P.T.O...

# Invertible 2-morphisms:

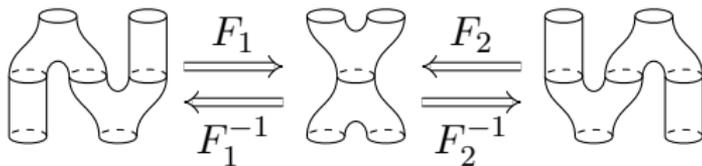

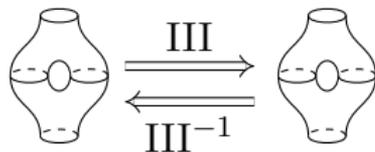

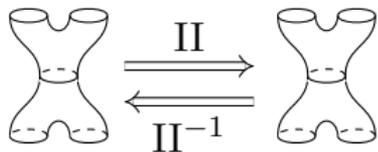

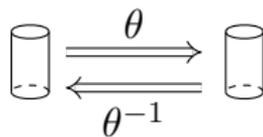

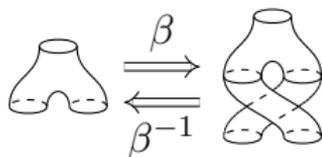

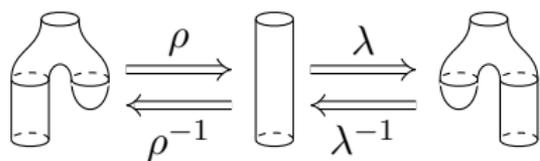

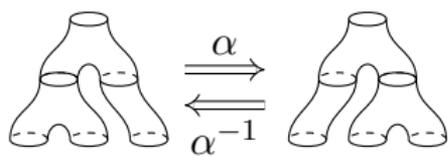

# Invertible 2-morphisms:

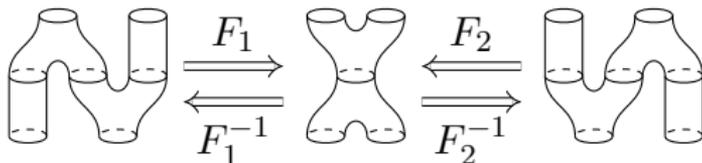

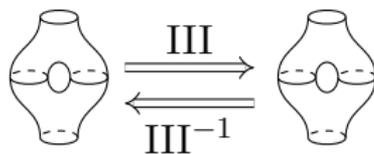

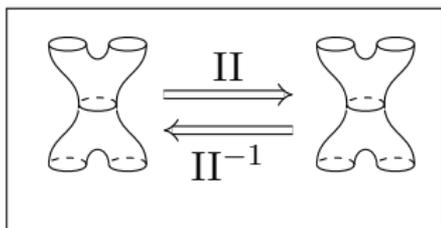

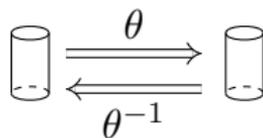

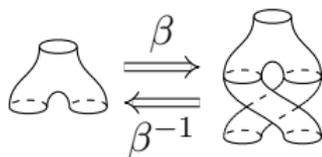

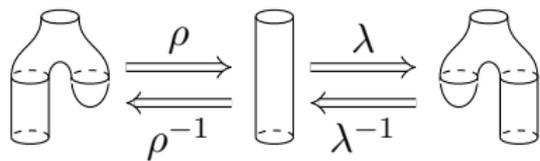

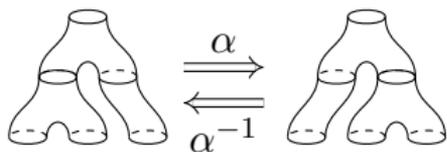

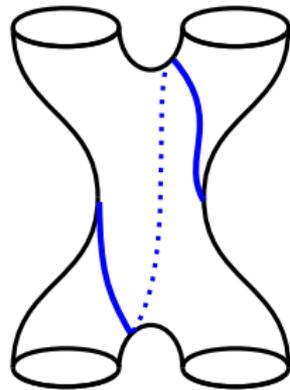

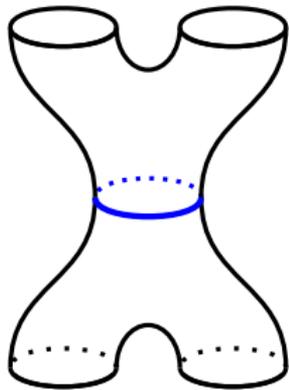

# Invertible 2-morphisms:

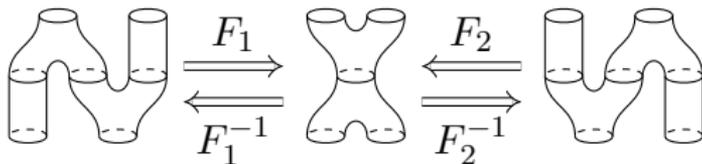

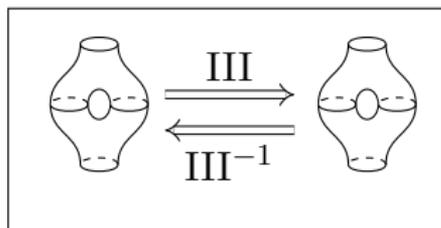

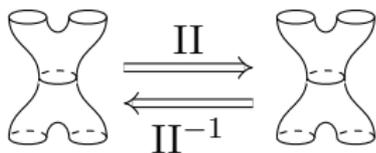

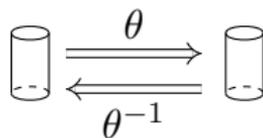

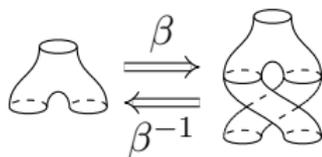

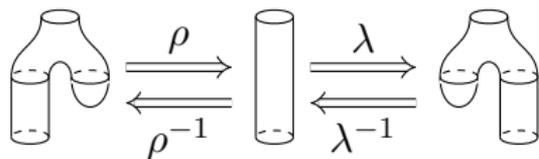

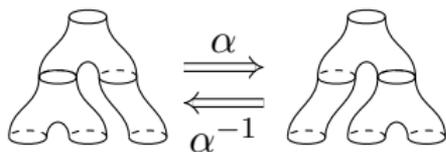

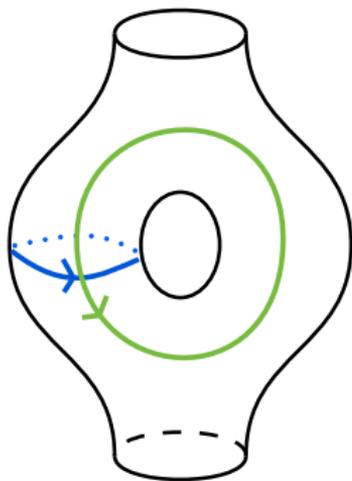

# Invertible 2-morphisms:

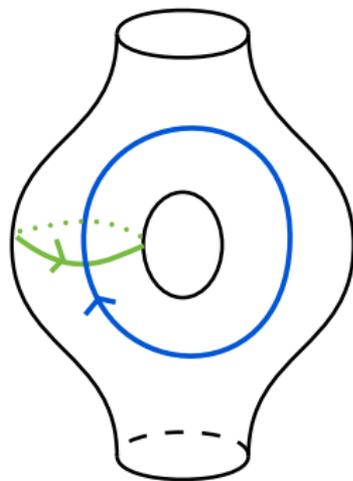

# Invertible 2-morphisms:

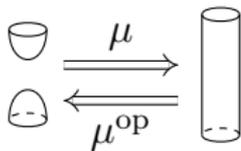

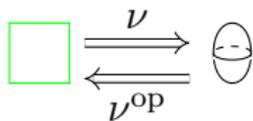

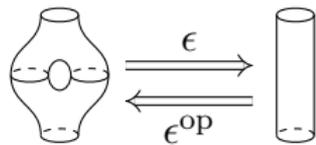

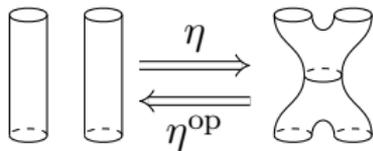

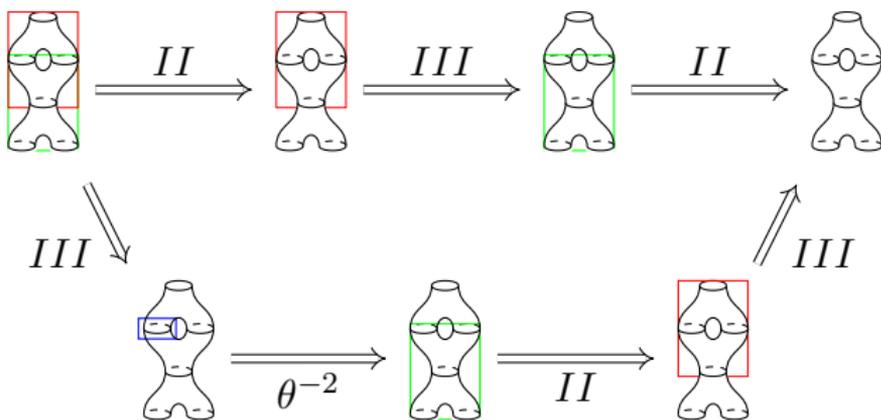

*III*  
⇒

Noninvertible 2-morphisms:

- Relations between the invertible generators, eg.

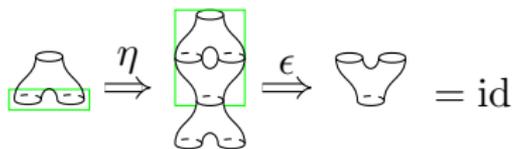

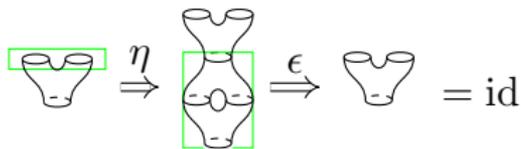

Compare with  $\underbrace{SL_2(\mathbb{Z})}_{\Gamma(\text{torus})} = \langle s, t \mid (st)^3 = s^2, s^4 = 1 \rangle$ .

- Relations between the non-invertible generators, eg.

$$\text{Pair of pants (top boundary boxed)} \xRightarrow{\eta} \text{Pair of pants (top boundary boxed, central circle)} \xRightarrow{\epsilon} \text{Pair of pants (single bottom boundary)} = \text{id}$$

$$\text{Pair of pants (bottom boundary boxed)} \xRightarrow{\eta} \text{Pair of pants (bottom boundary boxed, central circle)} \xRightarrow{\epsilon} \text{Pair of pants (single top boundary)} = \text{id}$$

- Relations between the non-invertible generators, eg.

**Proof.** Uses Cerf theory methods from Chris Schommer-Pries's thesis. ■

## 4. Modular tensor categories

**Defn.** A *modular tensor category* is a  $\mathbb{C}$ -linear semisimple ribbon category whose braiding is nondegenerate.

## 4. Modular tensor categories

**Defn.** A *modular tensor category* is a  $\mathbb{C}$ -linear semisimple ribbon category whose braiding is nondegenerate.

‘Ribbon’ means that there is a tensor product and nontrivial braiding isomorphisms  $V \otimes W \rightarrow W \otimes V$ , so the objects behave like braided ribbons when drawn in string diagrams:

$$\begin{array}{ccc} V \otimes W & & V \quad W \\ \downarrow \sigma & \text{drawn as} & \begin{array}{c} \text{---} \backslash \text{---} \\ \text{---} / \text{---} \\ \text{---} \end{array} \\ W \otimes V & & W \quad V \end{array}$$

## 4. Modular tensor categories

**Defn.** A *modular tensor category* is a  $\mathbb{C}$ -linear semisimple ribbon category whose braiding is nondegenerate.

‘Ribbon’ means that there is a tensor product and nontrivial braiding isomorphisms  $V \otimes W \rightarrow W \otimes V$ , so the objects behave like braided ribbons when drawn in string diagrams:

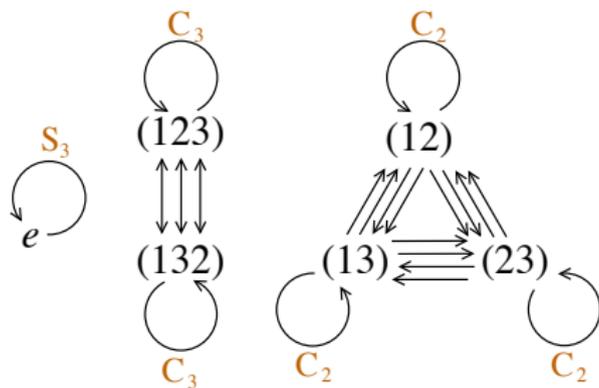

$$\begin{array}{ccc} V \otimes W & & V \quad W \\ \downarrow \sigma & \text{drawn as} & \begin{array}{c} \text{---} \backslash \text{---} \\ \text{---} / \text{---} \\ \text{---} \end{array} \\ W \otimes V & & W \quad V \end{array}$$

Examples: Representations of loop groups, representations of quantum groups.

Toy example: let  $G$  be a finite group. Let  $\Lambda G$  be the *loop groupoid* of  $G$ :

- ▶ An *object* of  $\Lambda G$  is an element  $g \in G$ .
- ▶ For every  $h \in G$ , there is an *arrow*  $g \xrightarrow{h} hgh^{-1}$ .

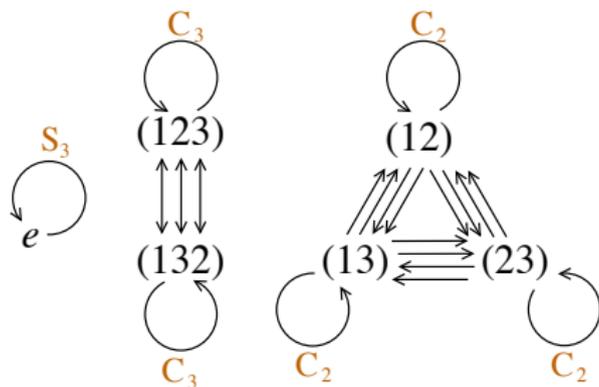

For example, here is a picture of  $\Lambda S_3$ :

Toy example: let  $G$  be a finite group. Let  $\Lambda G$  be the *loop groupoid* of  $G$ :

- ▶ An *object* of  $\Lambda G$  is an element  $g \in G$ .
- ▶ For every  $h \in G$ , there is an *arrow*  $g \xrightarrow{h} hgh^{-1}$ .

For example, here is a picture of  $\Lambda S_3$ :

$\text{Rep}(\Lambda G)$  forms a modular category.

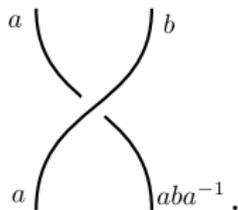

The tensor product on  $\text{Rep}(\Lambda G)$  is

$$(V \otimes W)_g = \bigoplus_{ab=g} V_a \otimes W_b$$

while the braiding  $\sigma : V \otimes W \rightarrow W \otimes V$  is given on homogenous elements by

$$v_a \otimes w_b \mapsto w_b \otimes V(a \xrightarrow{b^{-1}})(v_a).$$

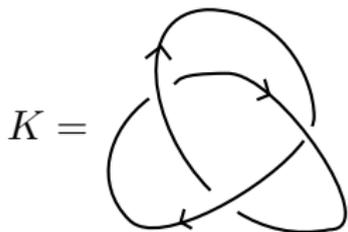

which is drawn as

By interpreting knot diagrams as knots in the modular category  $\text{Rep } \Lambda G$ , we get an invariant of knots  $Z$  based on representation theory of finite groups.

By interpreting knot diagrams as knots in the modular category  $\text{Rep } \Lambda G$ , we get an invariant of knots  $Z$  based on representation theory of finite groups.

For instance, given a representation  $V$  supported on a conjugacy class  $\mathcal{A}$  in  $G$ , the trefoil

computes as

$$Z(K) = \sum_{\substack{a, b \in \mathcal{A} \\ aba = bab}} [V^*(b^{-1} \sum_{ijk} a^{-1} \rightarrow)]_{kj} [V(a \rightarrow)]_{ki} [V^*(a^{-1} \rightarrow ba^{-1}b^{-1})]_{ji}$$

For instance, for  $G = S_3$ , and  $V$  the sign representation supported on the class of  $(12)$ , this gives 6.

## 5. Classification theorem

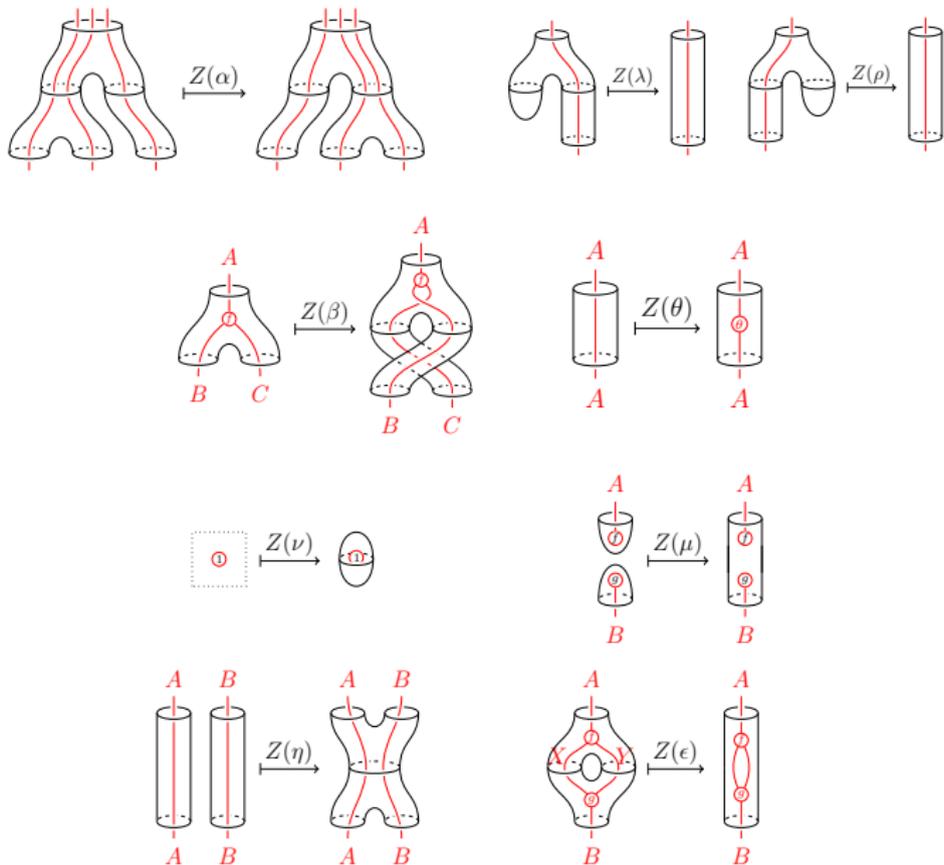

**Theorem.** [BB, CD, CS-P, JV] The 2-groupoid of oriented 1-2-3 topological quantum field theories is equivalent to the 2-groupoid of anomaly-free modular tensor categories.

## 5. Classification theorem

**Theorem.** [BB, CD, CS-P, JV] The 2-groupoid of oriented 1-2-3 topological quantum field theories is equivalent to the 2-groupoid of anomaly-free modular tensor categories.

Many ideas here in fact date back to the ‘early days’ of TQFT in the 1990’s. But a key aspect of our approach is a new ‘internal string diagrams’ calculus to check the relations.

**Lemma.** In any oriented 123 TQFT  $Z : \mathbf{Bord}_{123}^{\text{or}} \rightarrow \mathbf{LinCat}$ , the generators must act as follows:

$$\begin{array}{ccc}
 \text{Cylinder} & \xrightarrow{Z(\mu^{\text{op}})} & p \cdot \left( \text{Two cups} \right) \\
 & & \\
 \text{Sphere} & \xrightarrow{Z(\nu^{\text{op}})} & \frac{1}{p}
 \end{array}$$

$$\begin{array}{ccc}
 \text{Cylinder with red line} & \xrightarrow{Z(\epsilon^{\text{op}})} & \frac{1}{p} \cdot \left( \text{Sphere with red and green lines} \right) \\
 & & \\
 & & \xrightarrow{Z(\eta^{\text{op}})} \left\{ \begin{array}{l} \frac{p}{d_A} \cdot \left( \text{Cylinder with red line } A \text{ and } A' \right) \\ \quad \quad \quad \left( \text{Cylinder with blue line } B \text{ and } C \right) \end{array} \right. \text{ if } A = A' \\
 & & 0 \quad \quad \quad \text{if } \text{Hom}(A, A') = 0
 \end{array}$$

$$\begin{array}{ccc}
 \left( \text{Sphere with red lines } AB \text{ and } AB \right) & \xrightarrow{Z(\text{III})} & \frac{1}{p} \cdot \left( \text{Sphere with red and green lines } AB \text{ and } AB \right)
 \end{array}$$

Here,  $p = \sum_i \theta_i d_i^2$ . (In the finite group model,  $p = |G|$ ).

## 6. Sample calculations

Let's use the internal string diagram calculus to compute some invariants of 3-manifolds!

## 6. Sample calculations

Let's use the internal string diagram calculus to compute some invariants of 3-manifolds!

Let's start with  $S^3$ . One can build it by creating and then killing a 2-sphere:

$$\square \xRightarrow{\nu} \text{circle} \xRightarrow{\nu^{\text{op}}} \square$$

Using the internal string diagram calculus, we compute:

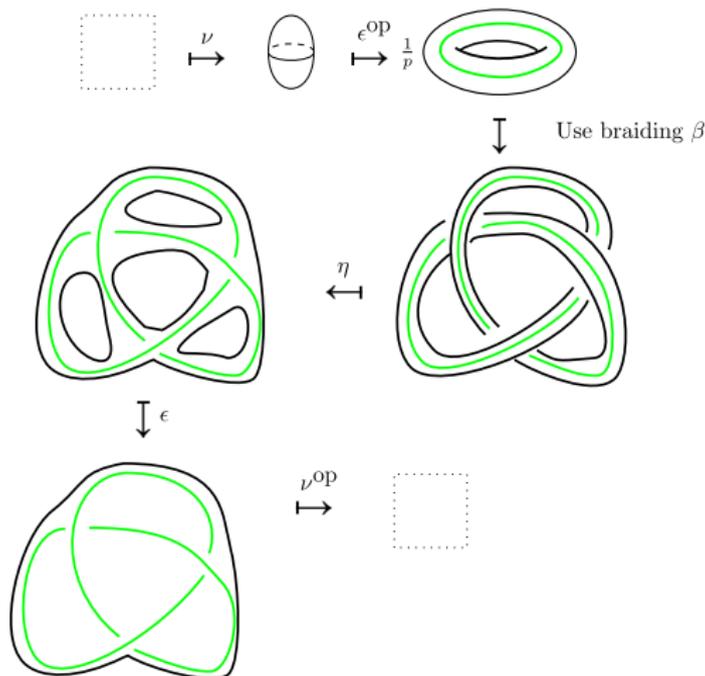

$$\square \xrightarrow{Z(\nu)} \text{circle} \xrightarrow{Z(\nu^{\text{op}})} \frac{1}{p} \square$$

So,  $Z(S^3) = \frac{1}{p}!$

Now suppose  $M_K$  is a 3-manifold obtained by surgery on a framed knot  $K \subset S^3$ . For instance,  $K$  might be the trefoil knot.

Now suppose  $M_K$  is a 3-manifold obtained by surgery on a framed knot  $K \subset S^3$ . For instance,  $K$  might be the trefoil knot.

We can build up  $M_K$  using the generators as follows:

So,  $Z(M_K) = \frac{1}{p^2} \sum_i d_i Z(K, V_i)$ . This shows that our approach is equivalent to the traditional surgery approach.

Topological quantum field theory can turn up some beautiful equations, since there are often different ways to compute an invariant.

Topological quantum field theory can turn up some beautiful equations, since there are often different ways to compute an invariant.

We have just seen that if  $G$  is a finite group, and  $K$  is the trefoil knot, then

$$Z(M_K) = \frac{1}{|G|^2} \sum_{\text{reps } V_i \text{ of } \Lambda G} \dim(V_i) Z(K, V_i).$$

Recall that earlier we computed  $Z(K, V_i)$  as a certain sum over the matrix elements of the representation  $V_i$ .

Topological quantum field theory can turn up some beautiful equations, since there are often different ways to compute an invariant.

We have just seen that if  $G$  is a finite group, and  $K$  is the trefoil knot, then

$$Z(M_K) = \frac{1}{|G|^2} \sum_{\text{reps } V_i \text{ of } \Lambda G} \dim(V_i) Z(K, V_i).$$

Recall that earlier we computed  $Z(K, V_i)$  as a certain sum over the matrix elements of the representation  $V_i$ .

There is a ‘dual’ way to determine  $Z(M_K)$  in terms of the homotopy group of  $M_K$ :

$$Z(M_K) = \frac{1}{|G|} |\text{Hom}(\pi_1(M_K), G)|.$$

Topological quantum field theory can turn up some beautiful equations, since there are often different ways to compute an invariant.

We have just seen that if  $G$  is a finite group, and  $K$  is the trefoil knot, then

$$Z(M_K) = \frac{1}{|G|^2} \sum_{\text{reps } V_i \text{ of } \Lambda G} \dim(V_i) Z(K, V_i).$$

Recall that earlier we computed  $Z(K, V_i)$  as a certain sum over the matrix elements of the representation  $V_i$ .

There is a ‘dual’ way to determine  $Z(M_K)$  in terms of the homotopy group of  $M_K$ :

$$Z(M_K) = \frac{1}{|G|} |\text{Hom}(\pi_1(M_K), G)|.$$

The fact that these two numbers are equal is rather interesting! For TQFT’s based on loop groups and quantum groups, these kinds of equations can be very striking.

# Summary

- ▶ We give a full, finite presentation of the symmetric monoidal 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  of oriented cobordisms.

# Summary

- ▶ We give a full, finite presentation of the symmetric monoidal 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  of oriented cobordisms.
- ▶ Using a new calculus of *internal string diagrams*, we are able to demonstrate the equivalence between oriented 123 TQFTs and anomaly-free modular tensor categories in a clean and efficient way.

# Summary

- ▶ We give a full, finite presentation of the symmetric monoidal 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  of oriented cobordisms.
- ▶ Using a new calculus of *internal string diagrams*, we are able to demonstrate the equivalence between oriented 123 TQFTs and anomaly-free modular tensor categories in a clean and efficient way.
- ▶ In particular, we show that the category assigned to the circle is actually *rigid*, resolving a long-standing issue. This uses the 2-categorical structure (the noninvertible adjunctions) in an important way.

# Summary

- ▶ We give a full, finite presentation of the symmetric monoidal 2-category  $\mathbf{Bord}_{123}^{\text{or}}$  of oriented cobordisms.
- ▶ Using a new calculus of *internal string diagrams*, we are able to demonstrate the equivalence between oriented 123 TQFTs and anomaly-free modular tensor categories in a clean and efficient way.
- ▶ In particular, we show that the category assigned to the circle is actually *rigid*, resolving a long-standing issue. This uses the 2-categorical structure (the noninvertible adjunctions) in an important way.
- ▶ Once a 3-manifold is presented in terms of the generators, computing its invariant is straightforward using internal string diagrams.
